The wave function of fermions, including electrons, is antisymmetric, meaning that it changes sign when two electrons are swapped; that is, $\psi(r_1, r_2) = -\psi(r_2, r_1)$, where the variables r_1 and r_2 correspond to the first and second electrons, respectively. Since the absolute value is not changed by a sign swap, this corresponds to equal probabilities.

Abstract. The relativity quantum theory of an electron moving in a given electromagnetic field, although successful in predicting the spin properties of the electron, yet involves one serious difficulty which shows that some fundamental alteration is necessary before we can regard it as an accurate description of nature. This difficulty is connected with the fact that the wave equation, which is of the form $[\nabla^2/c^2 + e/\hbar c A_0 + \frac{1}{\hbar c} (\nabla \cdot \mathbf{p} + e/c A) + \frac{1}{\hbar^2 c^2} 3mc^2] \psi = 0$, (1) has, in addition ...

Theory of electrons and positrons Nobel Lecture, December 12, 1933 Matter has been found by experimental physicists to be made up of small particles of various kinds, the particles of each kind being all exactly alike. Some of these kinds have definitely been shown to be composite, that is, to be composed of other particles of a simpler nature.

A SYMMETRIC THEORY OF ELECTRONS AND POSITRONS Note by Ettore Majorana Translated from Italian by Luciano Maiani* 'Il Nuovo Cimento' 14 (1937) 171-184 (Received April 20, 1981) The interpretation of the so-called "negative energy states" proposed by Dirac(1) leads, as it is well known, to a substantially symmetric description of electrons and positrons.

In his lecture, Dirac emphasizes that the procedure he came up with is successful in the case of electrons and positrons and that he hoped that in the future some such procedure will be found for the case of the other particles. He considered the electron and positron because in their case, the theory has been developed further.

Alternative Title: energy band Band theory, in solid-state physics, theoretical model describing the states of electrons, in solid materials, that can have values of energy only within certain specific ranges. The behaviour of an electron in a solid (and hence its energy) is related to the behaviour of all other particles around it.

The one-electron universe postulate, proposed by John Wheeler in a telephone call to Richard Feynman in the spring of 1940, is the hypothesis that all electrons and positrons are actually manifestations of a single entity moving backwards and forwards in time. According to Feynman: I received a telephone call one day at the graduate college at Princeton from Professor Wheeler, in which he said ...

Electrons are constituents of atoms; the number of electrons in a neutral atom is equal to the atomic number, that is, to the number of protons in the nucleus (see ATOM). The present values of the charge (e) and mass (m_e) of the electron are. $e = 4.803242(14) \times 10^{-10}$ cgse units = $1.6021892(46) \times 10^{-19}$ coulomb. $m_e = 0.9109534(47) \times 10^{-27}$ g

What is now often called Lorentz ether theory (LET) has its roots in Hendrik Lorentz 's "theory of electrons", which was the final point in the development of the classical aether theories at the end of the 19th and at the beginning of the 20th century. Lorentz's initial theory was created between 1892 and 1895 and was based on a completely motionless aether.
